10-21 symptoms. Much current research is aimed at better understanding the genetic basis and symptomatology of Tourette's, as well as its relationship to related disorders. The hope is that this research leads to better diagnostic tools and better treatments for Tourette's.	10-20 co-occurs with. An important role in Tourette's gene expression is played by the sex of the person. In particular, males affected by the gene are more likely to have ties and females who have a genetic predisposition are more likely to have obsessive-compulsive	14	Back	24	Back

10-18 inheritance characterized the condition, more recent studies discovered the pattern of inheritance was much more complex. Although there may be a few genes that have substantial effects, it's also possible that many genes with smaller effects and environmental factors may play a role in the development of Tourette's.
